UIAA MEDICAL COMMISSION

VOL: 2

Emergency Field Management of Acute Mountain Sickness, High Altitude Pulmonary Edema, and High Altitude Cerebral Edema

Intended for Doctors, Interested Non-medical Persons and Trekking or Expedition Operators

Th. Küpper, U. Gieseler, C. Angelini, D. Hillebrandt, J. Milledge

2012
1 Introduction

Acute mountain sickness (AMS), high altitude pulmonary edema (HAPE) and high altitude cerebral edema (HACE) are the most important and most common altitude-related diseases. Up to altitudes of about 5000-6000m, symptoms of altitude illness are a direct result of inadequate acclimatization. Dependent on the ascent profile, up to >70% of mountaineers may suffer from symptoms of AMS. Primary prevention is therefore considered the gold standard to avoid altitude illness. This includes a conservative ascent profile, adequate hydration and energy intake, and early recognition and management of potential medical problems, both before and during the trip.

This recommendation focuses on:

1. Situations where prevention has failed or other factors contributed to the development of AMS, HACE or HAPE (weather, rescue missions, predisposition etc) and;
2. On adult mountaineers (for children see UIAA Standard No. 9 [1])

Note 1: Since many trekking organizations do not follow an adequate altitude/time profiles [2], [1] prevention starts before booking! Check carefully the profile of your tour!

Note 2: An “adequate altitude/time profile” is defined in section 3 below.

2 Risk situations for AMS, HAPE, and HACE

2.1 Risk factors

- Inadequate altitude profile / ignorance of the needs of acclimatization
- Rapid ascent to high altitude
  - E.g.: airport of destination at high altitude, ascent by vehicle or undertaking an “aggressive” altitude profile while hiking. Note: The high camps of several expedition routes are situated within ~1000m of altitude difference. Here “yo-yo” tactics” (no overnight stay for the first ascent(s) to these camps) is recommended.
  - Team blocked at high altitude
  - “Re-entry problems” of people living at high altitude after visiting sea level for several days or weeks
- Previous History of AMS, HACE or HAPE
- Victim ignoring early symptoms of altitude illness
- Dehydration
- Elderly people (>65 years) showed a 3-fold higher risk for HAPE [3]. No such risk was found for AMS and HACE.
2.2 Altitudes and time frames

- Typical altitudes at risk:
  - >ca. 2,500 m for AMS
  - >ca. 3,000 m for HAPE
  - >ca. 4,000 – 5,000 m for HACE
  - **Note:** symptoms lower than the altitudes mentioned are rare, but even severe cases are possible!

- Typical time frame for symptoms
  - AMS: >4 hrs and <24 hrs after ascent to new altitude
  - HAPE (& HACE): >24 hrs
  - **Note:** Onset of AMS-symptoms <4 or >24 hrs, or HAPE-symptoms <24 hrs is rare, but possible!

3 Prevention of altitude diseases

- Acclimatize properly!
  - Above 2500-3000m the next night should not be planned more than 300-500m higher than the previous one
  - Have two nights at the same altitude after every 2-4 days of ascent. On this day you may climb higher, but return to sleep.
  - The use of drugs to prevent altitude symptoms should be restricted to some special situations, especially if a fast ascent cannot be avoided for any reason (airport of destination at high altitude, rescue operations) or when a person suffers from symptoms although he/she has followed an adequate altitude profile (so called “slow acclimatizer”). For several reasons, especially cost-effectiveness-risk-ratios, acetazolamide is recommended. Mostly 500 mg/day has been recommended, but the dose-responsiveness is limited and 250-750 mg/day has been proven to be nearly equally effective [4], [5], [6], [7], [8].

4 Clinical features

**Note:** Since all members of a team had a similar or even identical ascent profile there may be more persons suffering from altitude disease than the one in whom you made the actual diagnosis. Never forget the porters and guides: Nowadays most of them are lowlanders and may suffer from altitude diseases at least as much than the tourists or climbers do [9], [2]!
4.1 Typical symptoms of AMS

- Several of the following symptoms:
  - Headache (most often diffuse and non-localized, but other types of headache do not exclude AMS)
  - Sleep disorders
  - Loss of appetite
  - Dizziness
  - Listlessness
  - Peripheral oedema
  - Severe heart palpitation
  - Nausea or vomiting

  **Note:** Typical symptoms may not all be present, in a few cases even headache may missing

  **Note:** In case of severe listlessness or somnolence: consider HACE! (see below)

  **Note:** Dyspnoea at light workload or even at rest: consider HAPE!

4.1.1 Scoring systems

The **Lake Louise Symptom Score** (see Appendix 1) was primarily established to quantify the severity of AMS for scientific purposes (field studies). It may also be used for diagnostic purposes, but for field management of AMS the symptoms listed above and the consequences described below and in Appendix 2 are sufficient.

**Note:** AMS is a clinical diagnosis and should not be based on any scoring system only. Such systems may be used to quantify the severity of AMS.

4.2 Typical symptoms of HAPE

- Dyspnoea even at light workloads progressing to dyspnoea at rest
  - High breathing rate (>30/min. in 69% of the cases [10])

- Rapid decrease in performance (cardinal symptom!)
- Cough
- High pulse rate
- Chest tightness
- Bubbling breath, cyanosis and bloody/foamy expectoration in severe cases
- Mild fever
4.3 Typical symptoms of HACE

- Severe headache without response to usual painkillers
- Nausea and vomiting
- Dizziness
- Ataxia
  - Note: The heel-to-toe walking test is a very sensitive and simple field test which also helps to differentiate unclear situations (e.g. if people want to mask their symptoms)
- Altered consciousness, confusion or hallucinations
  - Irrational behaviour may indicate an early stage!
- Final stage: coma and death by respiratory paralysis
- Frequently there is loss of insight, by the patient, who may insist that they are all right and just wish to be left alone.

Note: Lay persons should always treat mountaineers for AMS, HAPE, HACE first, except if they are absolute sure that there is another reason for the symptoms. Doctors should also always consider AMS, HAPE, or HACE at (high) altitude first, but they should always take other diagnoses into account, especially those listed in the following tables.

Note: If it should be impossible for lay persons to decide whether a patient suffers from HAPE or HACE he should be treated for both.

5 Treatment

See also flow chart in appendix 2

5.1 Emergency management of AMS

5.1.1 Light to moderate symptoms

- Stay at the same altitude (rest day) until symptoms have completely disappeared
  - No further ascent with symptoms!
- Avoid any workload, especially with forced respiration during expulsion
- Treat symptomatically (oral therapy)
  - Nausea: antiemetics (e.g. dimenhydrinate)
  - Headache: paracetamol or ibuprofene (no acetyl salicylic acid (aspirin)) because of increased risk for bleeding and gastric ulcer
  - Acetazolamide 250mg (2x/day) may be considered if the above fail after 6-12 hours. Note: This drug is not considered to be a first line treatment of AMS anymore.
- Try to drink enough in spite of nausea
- Descend if symptoms do not improve or worsen within 24 hours
- Sleep with slightly elevated upper body
5.1.2 Severe symptoms

- Exclude HACE!
  - If there should be any doubt: Treat as HACE!
- Rest immediately, never continue ascent!
  - Protect patient against cold
- Treat symptomatically as described above
- Dexamethasone 8 mg
  - May be repeated after 6 hrs, if symptoms should be still severe
- Descent as soon as possible to the last camp or hut, where the patient was well (or at least about 500 (– 1,000) meters)
  - “As soon as possible” means, that the symptoms were significantly ameliorated before and the patient will be able to manage the terrain (distance, steepness…) safely
  - The patient shouldn’t carry loads while descending
  - Do not leave the camp to descend if there are ascents en route.
    - With severe symptoms the patient may be unable to manage even short ascents, even if they are short.
  - If possible, do not descent completely, otherwise there wouldn’t be any stimulus for acclimatization anymore
- If a portable hyperbaric chamber is available, refer to UIAA recommendation No.3 [11]
- No re-ascent before the patient feels completely well.

5.2 Emergency treatment of HAPE
(see also flow chart in appendix 2)

- Rest immediately, never continue ascent!
  - Upper body in upright position
  - Protect patient against cold
- Oxygen (if available)
- Nifedipine slow release, 20 mg
  - Onset of the effect after 10 – 15 min.
  - Repeat, if symptoms should worsen again
    - No time frame possible! Pure clinical decision based on symptoms.
  - Avoid using nifedipine short release! This may cause a severe decrease of blood pressure.
- Portable hyperbaric chamber
  - For use and tactics refer to UIAA recommendation No.3 [11]
- PEEP valve, if patient accepts it
- Leave high altitude
5.3 Emergency treatment of HACE
(see also flow chart in appendix 2)

• The management is the same as for HAPE but instead of Nifedipine give Dexamethasone as follows:
  o Dexamethasone
    • If the patient is conscious they should be given 8 mg orally every 6 hours until they are free of symptoms
    • In severe cases a parenteral initial dose of 8-10 mg (depending on size of ampoule dose) should be given either i.v. or i.m.
    • In extremes in adverse weather conditions this parenteral dose may have to be given i.m. through clothing to a moribund patient and under these circumstances higher initial doses have been tried. Preloaded ready to use syringes can be easier to handle and use in these adverse conditions
    • It is also possible to drink the ampoule’s content

• Additional acetazolamide 250mg bid may be an additional benefit

• While descending, pay more attention to the patient’s safety, especially in any case of dizziness or ataxia!

5.4 Emergency treatment of combined HAPE and severe AMS

• Manage as for both HAPE and HACE.
5.5 Emergency treatment of unclear situations

Sometimes there may be patents where the diagnosis of “pure” AMS, HAPE, or HACE is unclear. This may happen if lay persons have to make the diagnosis, but also for physicians some situations, e.g. with severe AMS/HACE but moderate HAPE. Here typical symptoms of HAPE may be masked by the predominating symptoms of AMS/HACE. Here UIAA MedCom recommends treating as for both, AMS/HACE and HAPE
Most important differential diagnoses in AMS and HACE

<table>
<thead>
<tr>
<th>Diagnosis</th>
<th>Patient’s history</th>
<th>Symptoms</th>
<th>Therapy</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exhaustion</td>
<td>Previous intense activity?</td>
<td>Impaired fitness, lack of motivation, impaired mood, headache. Severe cases: collapse.</td>
<td>Rest, refuel with carbohydrates, fluid, and cold protection. Severe cases: glucose i.v., passive transport</td>
<td>Eating complex carbohydrates are preferred to carbohydrates with a high glycaemic index to prevent the risk of hypoglycaemia occurring during treatment!</td>
</tr>
<tr>
<td>Dehydration</td>
<td>Hot climate, inadequate fluid intake, diarrhoea, vomiting</td>
<td>Thirst, lack of motivation, impaired fitness, headache, oliguria, dry skin and mouth, fever. Severe cases: tachycardia, collapse dizziness, delirium, seizures; urine colour often dark yellow</td>
<td>Rest and rehydrate! Slight hypotonic beverages are best. Severe cases: glucose 5%, potassium lactate, or NaCl 0.9% i.v. (at least 1000 ml, continued by oral rehydration)</td>
<td>Restoring a normal hydrated status may need several days! Lack of thirst does not indicate adequate hydration at altitude! Drink even when you don’t feel thirsty! The colour of urine does not indicate adequate or inadequate fluid balance (but urine volume of at least 1 l/day does)</td>
</tr>
<tr>
<td>Sunstroke</td>
<td>Exposure to intensive sunlight?</td>
<td>Meningitis-like headache, fatigue, dizziness, nausea, vomiting, tachycardia. Final stage: stupor, coma.</td>
<td>The victim should take no further activity. Place him in the shade or inside a room. Drink plentiful cool fluids. Take a painkiller.</td>
<td>Monitor the patient, situation may be life-threatening!</td>
</tr>
<tr>
<td>Heat stroke</td>
<td>Hot climate, inadequate fluid intake, lack of fitness combined with physical activity</td>
<td>Similar to dehydration, but with neurological symptoms and collapse, respiratory arrest and circulatory collapse. Hot skin</td>
<td>Rest in shade, cool patient, apply fluid to his/her clothing to increase evaporation, survey breathing and circulation. Passive transport.</td>
<td>Life-threatening situation! Allow time for appropriate heat adaptation before demanding activities are started!</td>
</tr>
<tr>
<td>Hangover</td>
<td>Previous intake of alcohol of any kind of wine / liquor?</td>
<td>Diffuse, non-localized headache, fatigue, nausea, lack of motivation</td>
<td>Give oral non-alcoholic fluid – if possible with electrolytes – or just wait. Survey patient!</td>
<td>Do not allow the patient to belay or to, lead. He won’t make good decisions! Note: Be warned that recent reports suggest excessive drinking is occurring more frequently in mountain huts.</td>
</tr>
</tbody>
</table>
Other (rarer) differential diagnoses

<table>
<thead>
<tr>
<th>Diagnosis</th>
<th>Patient's history</th>
<th>Symptoms</th>
<th>Therapy</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Seizures</strong></td>
<td>Ask about previous seizures! If patient is unconscious, comrades may be able to give information.</td>
<td>Localized or generalized attacks with sudden onset, sometimes aura or postictal semi-conscious state</td>
<td>Protect the patient from falls first, especially in the mountains! Diazepam rectally or i.v. in severe cases.</td>
<td>First seizure at altitude is an extreme rare event!</td>
</tr>
<tr>
<td><strong>CO intoxication</strong></td>
<td>Cooking or fuel powered lights inside of the tent or a snow cave</td>
<td>Headache, confusion.</td>
<td>Oxygen (if available) or fresh air (open tent or cave!)</td>
<td>Note: No cyanosis!</td>
</tr>
<tr>
<td><strong>Acute psychosis</strong></td>
<td>Psychic or psychiatric history?</td>
<td>Complete loss of control of acceptable behaviour, resulting in extraordinary risk for the patient and possibly other group members in the mountains.</td>
<td>Sedative or antipsychotic drugs in severe cases. Note: some drugs may impair breathing, especially if used at altitude!</td>
<td>First episode of a psychiatric disease at altitude in patients without any psychiatric history is an extreme rare event!</td>
</tr>
<tr>
<td><strong>Stroke</strong> (TIA / progressive stroke)</td>
<td>In most cases no special history</td>
<td>More or less sudden onset of paresis, speech impediments, and other neurological symptoms</td>
<td>In regions with some infrastructure (e.g. Alps): Passive transport to hospital as soon as possible. On some expeditions passive transport is not appropriate, but most cases recover within 24-48 hours. In any case: monitor patient, stabilize blood pressure in case it becomes &gt;200/100 mmHg</td>
<td>Potentially life-threatening situation!</td>
</tr>
<tr>
<td><strong>Brain tumour</strong></td>
<td>In most cases no special history</td>
<td>More or less sudden onset of paresis, speech impediments, and other neurological symptoms. Normally misinterpreted as stroke / TIA (see above)</td>
<td>Cortisone i.v. (high dosage). Stabilize blood pressure in case it becomes &gt;200/100 mmHg. Monitor patient. Passive transport to hospital as soon as possible.</td>
<td>If no history of tumor / metastases is known, this diagnosis is almost impossible to make in the field.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Diagnosis</th>
<th>Patient’s history</th>
<th>Symptoms</th>
<th>Therapy</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypoglycaemia</td>
<td>Diabetes?</td>
<td>Hunger, nausea / vomiting, tachycardia, restlessness / tremor, sweat, impaired fitness, lack of motivation, impaired mood, dizziness, mydriasis, hypertension</td>
<td>Rest and feed complex carbohydrates (oligosaccharides). Measure blood glucose concentration every 15 min. until patient is fine and concentration is stable &gt;60 mg/dl (&gt;3.3 mmol/l).</td>
<td>Significant hypoglycaemia without diabetes is a very rare event and normally not induced by physical activity!</td>
</tr>
<tr>
<td>Diabetic ketoacidosis</td>
<td>Only in diabetic patients. With modern therapy rare, but possible if the diabetic problem is combined with fluid loss (e.g. traveller’s diarrhoea or high altitude dehydration). Note: Specific risk for diabetic mountaineers: Acetazolamide (contraindication for diabetic patients!)</td>
<td>First signs similar to Dehydration (see there). Severe cases: tachycardia, hypotension, oligo-anuria, hyperglycaemia</td>
<td>Potentially life-threatening situation! Monitor patient continuously! Rehydrate patient (NaCl 0.9% i.v., 1000 ml 1st hour, continued according to symptoms). Rapid acting insulin &quot;low dose scheme&quot; (20 E i.v. as bolus, followed by 5 – 10 E/hr i.v.) until blood glucose concentration is &lt;250 mg/dl (&lt;13.9 mmol/l). Transport to hospital as soon as possible.</td>
<td>Devices to measure blood glucose concentration give false-low results if used at &lt;14°C (&lt;0°C no measurement possible). Note: bicarbonate administration in the wilderness without lab results is very risky! It may induce extreme hypokalaemia</td>
</tr>
<tr>
<td>Hyponatriaemia</td>
<td>Intake of high amounts of salt-free beverages (water, tea…), normally in hot climate or in cases of traveller’s diarrhoea.</td>
<td>Impaired fitness, lack of motivation, impaired mood, dizziness, syncope, collapse. Salt stained clothing or sweat stings eyes.</td>
<td>Rest. Give oral rehydration solution, or beverages with a small pinch of salt. If severe, administer hypertonic mannitol, i.v. hypertonic NaCl 3% at rate 1-2 ml/kg/hr.</td>
<td>Allow time for appropriate heat adaptation before demanding activities will be started! Do not drink excessive quantities of water or plain tea.</td>
</tr>
<tr>
<td>Meningitis / Encephalitis</td>
<td>No special history in most cases (contact with persons who had similar symptoms some days ago?)</td>
<td>Massive, meningitis-like headache, fatigue, dizziness, nausea, vomiting, tachycardia, fever. Final stage: stupor, coma.</td>
<td>Antibiotics, painkillers. Take care for your safety and that of the group’s - the patient should wear a mask! Transport to hospital as soon as possible.</td>
<td>Survey patient! Note: situation may be life-threatening!</td>
</tr>
<tr>
<td>Intoxication / drug abuse</td>
<td>Intake of any drug or plant?</td>
<td>Several neurological / psychiatric symptoms, depending on the drug used.</td>
<td>Monitor patient (circulation, breathing). Cold protection.</td>
<td>Treatment with specific drugs is normally not realistic in the mountains.</td>
</tr>
</tbody>
</table>

A total of > 3 points indicates AMS (if no evidence for other reason of symptoms)

**Note:** For scoring systems for children see UIAA Consensus Paper No.9 “Children at Altitude” [1]
7 APPENDIX 2:
AMS is a serious medical condition which can quickly lead to HACE which is a life threatening emergency. Any signs or symptoms should be reported to expedition leader. All symptoms at altitude must be considered as altitude related until proven otherwise.
**HACE**
- Severe headache
- Incoordination
- Behaviour change
- Hallucination
- Ataxia
- Disorientation
- Confusion
- Lower consciousness

**HEADACHE**
- Simple pain-killer

**AMS**
- Headache + one of the following
  - Loss of appetite
  - Nausea
  - Vomiting
  - Lethargy
  - Sleep disturbance
  - Dizziness

**HAPE**
- Breathing difficulty
- Reduced exercise tolerance
- Cough; sometimes "wet"
- Blood stained sputum

---

**DESCRIPTIVE CHART**

**HACE**
- Severe headache
- Incoordination
- Behaviour change
- Hallucination
- Ataxia
- Disorientation
- Confusion
- Lower consciousness

**HEADACHE**
- Simple pain-killer

**AMS**
- Headache + one of the following
  - Loss of appetite
  - Nausea
  - Vomiting
  - Lethargy
  - Sleep disturbance
  - Dizziness

**HAPE**
- Breathing difficulty
- Reduced exercise tolerance
- Cough; sometimes "wet"
- Blood stained sputum

---

**Descend Oxygen**

**Dexamethasone**
- 8mg initially (orally or im/iv if unconscious)
- then 8mg/6hrs
- GAMOW bag

**Stop Further Ascent**

**Rest**

**Simple Pain-Killer**

**Antiemetic**

---

**No Improvement**

**Worsens**

**Descend Oxygen**

**Dexamethasone**
- 8mg every 6 hours orally or im/iv
- GAMOW bag

---

**Descend**

Any person found or becoming unconscious at altitude should be given Dexamethasone by injection.

History of this recommendation paper
The first edition was written by O. Öltz (1996). At the UIAA MedCom Meeting at Snowdonia in 2006 the commission decided to update all their recommendations. The version presented here was approved at the UIAA MedCom Meeting at Adršpach – Zdoňov / Czech Republic in 2008.

The actual update was finished in spring 2012 and approved at the UIAA MedCom meeting at Whistler, Canada, in July 2012.
